FILM STRIP

A color film strip that includes all the charts in this book can be purchased for \$4.00 from the address given below. The film strip is so designed that the charts can be cut apart and mounted as separate 2- by 2-inch slides.

An interpretation of the charts is given in the text of this chart book, a copy of which will be sent to every person ordering a film strip. One copy of the film strip and the chart book is being sent to the Extension Editor in each of the 48 States and Territories.

IMPORTANT

When Ordering Film Strips:

Send order and remittance (\$4.00) to Photo-Lab., Inc.,
3825 Georgia Avenue, N. W., Washington 11, D. C.
Do not send order to Bureau of Human Nutrition and
Home Economics.

Rural Family Living

POPULATION

Of the 39 million families in the United States in 1950, 13 million were rural families--about 6 million of these lived on farms (chart 1). There were twice as many urban as rural families--26 million.

The Nation's families were unevenly distributed by regions. Ten million resided in the Northeast, 12 million in the North Central States, 12 million in the South, and 5 million in the West.

Over four-fifths of the rural farm families were concentrated in the South and North Central regions. These two regions also contained two-thirds of the Nation's rural nonfarm families so that about three-quarters of the Nation's rural

families (farm and nonfarm) were concentrated in these areas.

While about 14 percent of the Nation's families were rural farm families, they made up 24 percent of all families in the South, 16 percent of all families in the North Central States, but only 10 percent of all families in the West and 5 percent of all families in the Northeast.

In the past hundred years, both the number of households and the size of population have grown tremendously. The number of households in the U. S. in 1950 was about 12 times what it had been in 1850 whereas the population was about 6 times what it had been in the earlier year (chart 2). The relatively greater increase in

number of households than in population is not a phenomenon of recent years. In each of the two half centuries from 1850 to 1950, the number of households increased more rapidly than did the size of the population.

The difference in the rate of increase of households and population is due primarily to the great increase in small-sized households (those with 1 or 2 persons) and medium-sized households. Many households now consist of only one person. Married couples try to maintain their own households; and aged parents and grandparents also strive to maintain their own households rather than become a part of the households of married children.

Though size of the population is more important in determining demand for food and clothing, number of households is more important in determining demand for dwelling units, household furnishings, equipment, and, to a lesser extent, demand for housing facilities--plumbing, lighting, heating.

From the standpoint of family relations, there are many advantages in the maintenance of separate households, but the choice of the smaller size of household as the preferred way to live means a higher cost for maintaining a given population at a given level of living. For one thing, it may mean that the services of a full-time homemaker are less effectively used than if

she were caring for a larger-sized household.

Furthermore, the social independence of the family means that the small, closely-related family tries to be economically self-sufficient from the date of marriage to the end of the parents' lives. Loss of income, due to unemployment or death of the father, may place an unusually heavy burden on the small family; costs of medical care and burial may be catastrophic. When families have more earning adults, the welfare of the family is not so likely to be jeopardized by such economic hazards. Also, such items as baby sitting and simple nursing care, which formerly could be provided by household labor, have tended to become money costs to the small parent-child family.

The timing of the family cycle is also changing, which in some ways accentuates the economic burden of the parent-child family. Evidence of this is presented in chart 3 where pertinent figures are given for the years 1890, 1940, and 1951. The median age of the husband at first marriage was reduced from 26 in 1890 to 24 in 1940 (and to 23 in 1951). It is generally more difficult for a younger husband to provide economic independence for his family than for an older man who is more likely to be established in an occupation. Furthermore, the life span has been lengthened markedly since 1890, so that more provision is necessary for old age.

However, some changes which are occurring tend to mitigate the economic burden of the parent-child family. Increasing urbanization of the population may increase a younger man's chances of supporting a family without a capital investment such as would be considered desirable on farms. Furthermore, between 1890 and 1940 there was a decrease in the age of parents at the time of completion of their families, partly as a result of a decrease in age at marriage and partly because fewer children were born. These factors also led to a reduction of about 5 years in the length of the period between the birth of the first child and the marriage of the last.

Increases in the average length of life have made striking reductions in the probability of children being orphaned and have tended to increase the duration of marriage. In 1890, either the husband or wife was likely to have died before the last child was married whereas in 1940 there were probably 11 years intervening between the marriage of the last child (when the father was 53 years old) and the death of one of the parents. Thus, there was a period when the parents might be able to accumulate for their own old age after the marriage of their last child.

The importance of the older age groups in the total population is shown in the table on page 11. In 1951 about 7 percent of all persons in the rural farm and 8 percent of the urban population were 65 years old or over. The group

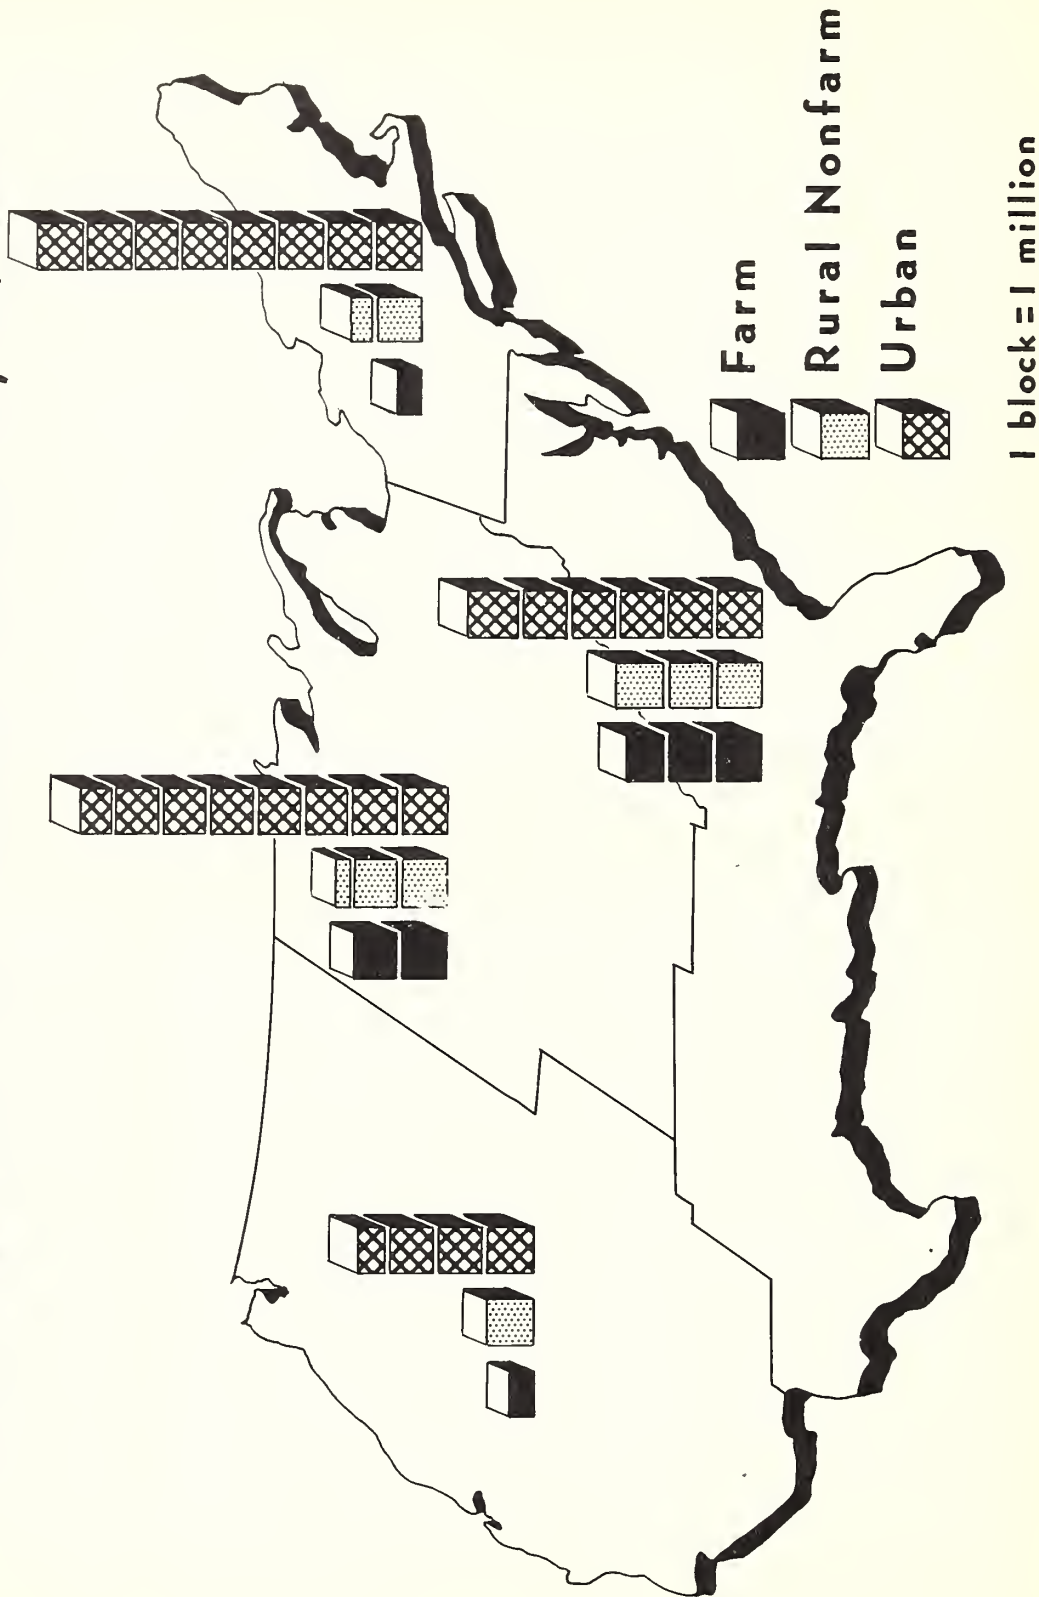

aged 55-64, most of whom were married and a large proportion of whom are presumed to have been free of the support of children, was about 9 percent of the rural farm and 9 percent of the urban group.

However, the younger age groups are also becoming increasingly important in the total population due to the high birth rates that have prevailed in recent years (chart 4). The relative increase in the birth rate in the past decade has been much greater for the urban population than for the rural farm population.

There are still significant differences between the rural farm and the urban groups in the proportion of children in the total population, though the differences were probably not as great in 1951 as in 1940. For each child under 14 in the rural farm group in 1951, there was one adult under 55 who was married, widowed, or divorced whereas in the urban group there were two such adults for each child. Most of the persons responsible for the support of the children were included in this group.

Other population differences between the rural farm and the urban groups are evident in chart 4. The proportion of widowed or divorced persons is larger in the urban than in the rural group. Single adults over 19 years old form a smaller part of the farm population than of the urban. There is a pronounced scarcity of single young women on farms.

INCOME

Of all families--both urban and rural--in the United States, 11 percent obtained more income from agricultural sources than from nonfarm sources in 1950. Eighty-three percent had nonfarm sources as their major source of earnings and about 7 percent had no earnings (chart 5).

In 1950, the major part of the earnings of a sizable number of families living on farms came from nonfarm sources. One-third had more money earnings from nonfarm sources than from farming when the earnings of all family members were included. For most of these families, earnings from nonfarm wages or salaries were more important than earnings from nonfarm self-employment (table, p. 15). Of the families living on farms whose major source of earnings was agriculture, a sixth received more from farm wages and salaries than from farm operation.

Some probing might well be done as to why such a large group--one-third--of the families living on farms were classified as having more income from nonfarm than from farm sources. Many of those families probably had substantial earnings from farming; therefore, some may have been classified in this group by a narrow margin. Furthermore, this proportion undoubtedly would be lower if nonmoney income were included.

Median family money income (before personal taxes) of all families living on farms in 1950 was about \$1,950 compared with about \$3,050 for rural nonfarm families and \$3,650 for urban families (chart 6).

The families living on farms who received the major part of their earnings from nonfarm sources had higher incomes than those whose major source of earnings was from agriculture. The median income was \$2,500 for the first group as against \$1,800 for the second. Of the families living on farms whose major source of income was agriculture, those who received more from farm operation had a median income of \$1,950 and for those who received more from farm wages it was \$1,450 (table, p. 17).

The earnings of farm wives account for part of the nonfarm income as well as part of the farm income of farm families. In April 1951, one-fifth of all farm wives were employed for cash wages, or were working as an unpaid family worker on the farm or in a family business for at least 15 hours during the week, or were seeking employment. This compares with 23 percent of rural nonfarm wives and 27 percent of urban wives (table, p. 19). Had the survey on which these figures were based been made in the sum-

mer rather than in April, the percent of farm wives employed would probably have been higher. Farm employment for farm women is much more seasonal than nonfarm employment for farm women or employment for women living in other areas.

That the wife's employment is related to residence is further indicated when families in which the husband's income was between \$2,000 and \$4,000 are studied. When the husband received that amount, one-fifth of the farm wives were employed, compared with one-quarter of the rural nonfarm wives, and almost a third of the urban wives (chart 7).

Taking all factors into consideration, it appears probable that, at a given income of the husband, it was less likely that the farm wife than that the urban wife would be regularly employed, full- or part-time. The lack of nonfarm jobs for farm wives in some areas and the dis- tance of nonfarm employment from their homes may make it more difficult for the farm homemakers to combine homemaking and regular employment. Higher levels of living achievable with a given money income on the farm than in the city may be part of the reason for the difference. The larger amount of housekeeping and chores carried on by many farm wives and the lesser facilities and equipment for easing their work may also help to account for the difference.

How much the husband earns influences whether or not the American wife takes a job. When the husband's income was under \$2,000 in 1950, 29 percent of the wives were employed or seeking

employment in April 1951. When the husband's income was \$2,000 to \$4,000, 27 percent of the wives were employed; but when the husband's income was \$4,000 to \$6,000, only 19 percent of the wives were employed.

However, the decrease in the percent of wives employed as the husband's income increased was less for farm than for urban families. When the husband's income increased from "under \$2,000" to "\$4,000 to \$6,000," the percent of farm wives employed declined from 23 to 16, whereas for urban wives the decline was from 34 to 20 percent.

Farm families are still more numerous in the lower money-income groups of all families in the United States than in the upper money-income groups. When all families in the United States are divided into thirds, rural farm families are a quarter of the lowest-money-income third, and only one-twentieth of the highest-income third (chart 8).

In contrast, urban families made up only one-half of the lowest-income families, two-thirds of the middle-income third, and three-quarters of the highest-income third.

The third of all families in the United States with the lowest incomes included less than a third of the white families, but two-thirds of the nonwhite families (table, p. 21). On the other hand, the third of families with the highest incomes included more than a third of the white families, but only 8 percent of the non-white families.

PRICES

The sharp rise in consumer prices, which began in June 1950 with the opening of hostilities in Korea, was halted in the early months of 1951. From then until the middle of 1952, prices tended to drift upward only slightly. In the 9 months from June 15, 1950 to March 15, 1951, the Index of Prices Paid by Farmers for commodities used for family living had increased 11 percent, whereas from March 15, 1951 to June 15, 1952--a span of 15 months--the increase was only 1 percent (table, p. 25).

The Consumers' Price Index for Moderate-Income Families in Large Cities showed the same general upturn. From June 15, 1950 to March 15, 1951, the increase for all family living items was 8 percent; from March 15, 1951 to June 15, 1952, only 3 percent (table, p. 27).

However, beginning in the early part of 1951, there was considerable variation in retail price movements as between different commodities and

services used for family living (charts 9 and 10). Food, because it is the largest component of each of the two indexes and therefore influences the all-item figures the most, tends to parallel the all-item index. Food prices reached new highs in the summer of 1952. Clothing prices rose markedly in the fall of 1951 with the introduction of the fall and winter lines. During the spring and summer of 1952, clothing prices declined considerably. House furnishings also declined during the spring of 1952. The Bureau of Agricultural Economics index of prices of home building materials and housing dropped after June 1951. Prices of autos and auto supplies showed a marked increase during the fall months of 1951. The rent index for city families has been increasing steadily for many months. The miscellaneous group of the Consumers' Price Index, which includes transportation, medical care, household operation, recreation, and personal care, has also increased steadily throughout the period beginning in June 1950.

The tendency of prices of consumer goods to level off or to increase only slightly beginning in early 1951, was due in part to a lessening in consumer demand. The waves of scare buying that occurred in the summer of 1950 and again during the following winter had left many consumers well stocked with durable goods. It is probable that many replacements of durable goods were made ahead of time. Furthermore, the fear of further price increases was allayed by the passing of a general ceiling price regulation in January of 1951. Retailers, who had anticipated continued buying on the part of consumers, found their inventories had mounted to extraordinarily high levels. Shortages at the manufacturing level failed to materialize. Thus, with store shelves well stocked and consumer buying falling off, the increase in retail prices was slower.

During the fall months of 1952 retail prices in general probably will continue to rise gradually. An indication is the Bureau of Labor Statistics weekly wholesale price index, which rose slightly during each of five successive weeks beginning with the second week in July 1952 following a long period of slow decline. Both farm and industrial products shared in this advance. Consumer incomes have risen during the past 2

years. Goods accumulated during the period of forward consumer buying in the summer and early winter of 1950 are now used up or being worn out. The cessation of steel production during the late spring of 1952 restricted the production of some durable consumer goods. Retail store inventories have been reduced from the high levels achieved in 1951. Price control legislation was extended only until April 30, 1953, and ceilings on fruits and vegetables in both fresh and processed form were specifically prohibited. Furthermore, the Defense Production Act Amendments of 1952 removed controls on consumer credit. Housing credit controls were relaxed by the Federal Reserve Board in June.

In general, consumer prices are now at about their highest level in history. Though prices of some goods as of June 15, 1952 were slightly lower than they had been a few months before, prices of other goods rose to new highs. For June, the food and tobacco component of the Index of Prices Paid by Farmers for Family Living was 20 percent above the lows of the late months of 1949 and early months of 1950. Clothing prices had increased 9 percent during the same period, home furnishings 12 percent, and building materials and housing 15 percent.

FAMILY SPENDING

Spending for family living in the country as a whole was much higher in 1951 than in 1950 or 1949. Total consumer expenditures averaged \$1,350 per person in 1951 as against \$1,280 in 1950 and \$1,210 in 1949. However, because of rising prices, the volume of goods and services purchased per person in 1951 was probably a little smaller than in 1950, though somewhat larger than in 1949.

The volume of consumer purchases in 1950 was unusually high because of the wave of scare buying that occurred between July and September and the second wave that started in December. In 1951, after February, buying leveled off in spite of increasing income. Many households were well stocked with durable goods and the imposition of a general ceiling price regulation in early 1951 reduced fear of further price rises.

That farm families as well as nonfarm families increased their spending in 1951 is shown by reports from farm families in three North Central States who submit accounts each year to State Universities or Colleges (chart 11). The dollar spending level of farm families in 1951 set a new record slightly higher than their previous high of 1948. Farm families, like all United States families, probably purchased a smaller volume of goods and services per person in 1951 than in 1950. Unlike the average for all United States families, the average volume of goods and

services purchased by farm families in 1951 was probably smaller than it had been in 1949. The decrease from 1950 to 1951 continued a decline from 1947. However, spending of farm families in real terms was still nearly 30 percent higher than just before the war.

In the years following World War II, fluctuations in the total spending of these farm families have been much more marked than in the average spending for the country as a whole. For the categories shown separately, the fluctuations in farm spending were especially marked for furniture and household equipment. On the other hand, farm family food expenditures followed closely the shifts in average spending of non-farm people.

For all U. S. consumers, average expenditures are more variable for durable goods than for non-durable. When durable goods were again available on the market following World War II, they accounted for large increases in family expenditures. In the last 2 years expenditures for durable goods have formed a major portion of the increased spending during periods of scare buying and decreases in these expenditures have been responsible for a large part of the subsequent downturn. Spending of the average farm families for furnishings and equipment was up a little in 1951 whereas the U. S. average declined somewhat.

Of the nondurable goods, food and clothing were the categories for which average spending was up in 1951 for the selected farm families and all United States families alike. Food expenditures showed the strongest increases from 1950 to 1951 as both groups continued to maintain the quantity of their food purchases in spite of higher prices.

Levels of spending by farm families vary widely from one part of the country to another, and the way farm families divide their spending among various budget categories also varies geographically. Differences in spending levels are related to regional differences in income, prices, and type of farming. The latter affects markedly home production of food and therefore spending for food. Spending differences are also related to size of family, degree of urbanization, climatic conditions, custom, and what is deemed desirable with respect to the content of living.

Six studies made by the Bureau of Human Nutrition and Home Economics in recent years in various parts of the country indicate the geographic variation in average expenditures (chart 12). To show the geographic variation more clearly with studies made at different times, the data have been put in terms of dollars with the same purchasing power, in this instance June 1952 dollars.

Of the four categories of spending considered, the greatest regional variation in average spending is found in food. The Tennessee food expenditures are low because of high amounts of home-produced food used and low income. Conversely the highest food expenditures in the areas studied occurred in the 4 Kansas counties

where many Kansas wheat farmers had little or no home food production and the level of income was high.

Clothing expenditures vary less from area to area. Since only a small part of the farm family's clothing is home-made, regional differences in home production do not affect expenditures for clothing as much as for food. Income differences are probably the largest single factor accounting for the differences in the areas studied.

Medical care expenditures show somewhat more variation than clothing but less than food. The range is only partly explained by differences in income, prices, and family composition. Also important are relative availability of medical personnel and facilities and customary standards of care.

In the figures given from these studies, data from the four Kansas counties and the two Minnesota counties are for families of a smaller size and probably with lower income than the average of all families in these areas and thus may understate the expenditures of all families by approximately 5 to 10 percent. Thus, the geographic variation is understated somewhat. On the other hand, adjusting the average expenditures reported for changes in the price level since the date of the survey only takes care of part of the problem of estimating possible ranges in 1952 farm family spending. In Southern areas, such as Mississippi and Tennessee, income increases since 1944 and 1945 may have resulted in higher family living expenditures. To this extent the regional variation in average expenditures is overstated.

1/ Kansas, families of husband and wife and 0 to 2 children under 22 years. Minnesota: Food, housekeeping families of 2 persons 16 years or older and 0 to 2 children 2-15 years; clothing, husband and wife and 0 to 2 children 2-15 years. Tennessee: Families of 2 or more persons. Montana, Illinois, and Mississippi, all families and single farm operators.

2/ Excludes food for boarders and farm help in each area except Montana.

3/ For Minnesota and Kansas counties, net farm plus nonfarm money income, after taxes. For Illinois, net farm money income adjusted for inventory change plus nonfarm money income, after taxes. For Tennessee, net farm plus nonfarm money income. For Mississippi counties, net farm money income adjusted for inventory change and depreciation plus nonfarm money income. Taxes referred to are personal property and income.

4/ In year-equivalent persons.

5/ Not available. Average gross farm money income of Montana farmers surveyed was \$8,186.

6/ Estimate for a spring week multiplied by 52.

7/ Expenditures for survey period were adjusted to June 1952 dollars using the Index of Prices Paid by Farmers for food, clothing, and household operation and the Consumers' Price Index for medical care. Both are national indexes. If current income were inflated to provide the same purchasing power in June 1952 as in the year surveyed, the income figures for the earlier studies would have to be increased by about 40 percent and those of the later studies by about 10 percent. Such estimates, however, do not reflect changes in the actual income level of families in these areas.

8/ Living on farms in open country throughout schedule year, Ford, Gray, Meade, and Edwards Counties.

9/ In 4 Kansas counties excludes laundry, rent of freezer locker, and supplies.

10/ Meeker and Wright Counties.

11/ Household size based on 1 week, not family size for year.

12/ Farm operators selling \$200 or more worth of products, Lee and Jones Counties.

FOOD CONSUMPTION

A substantial part of the farm family's food is raised on the home farm in many areas. Studies made in seven selected areas scattered over the Midwest and South from 1944 to 1949 show that from a third to two-thirds of the average money value of food comes from home production (chart 13). A lower proportion may be home produced in other type-of-farming areas as in an area specializing in wheat.

The proportion of farm family food from home production varies among these seven areas, as well as among families within any one area. Income level and economic pressure, size of the family, labor available, and type of farming operations are among factors that affect the extent of food production for home use. The fact that the studies were made in different years is responsible for some of the difference among these studies; in general more food for family use was produced at home during World War II than in the years since.

In spite of the fact that large amounts of home-produced food are still typical of farm families today, the trend in home production is probably downward. The evidence of the trend from 1929 to the present, however, is not clear cut.

From 1929 to 1939, the picture was affected by the depression, drought, and low farm income.

The percent of farms with home gardens and the percent with milk cows increased during those years (chart 14 and table, p. 41).

During the 1940's, wartime shortages and rationing affected the picture. The proportion of farms having a garden increased when the war program was in high gear and then declined from 1944 to 1949. The proportion of farms with milk cows fell from 1939 to 1949 (chart 15). From other data, we know that it was about constant in the first half of the decade and that the drop came in the second half. Probably the trend in farm slaughter of meat animals was similar; over the decade as a whole, it fell (table, p. 43). There was less pressure to raise much of the family's food in 1949, when food supplies were ample generally, than during World War II. Although the average income of farm families was lower in 1949 than it had been in the preceding years, it was still high compared with prewar years.

The evidence available suggests that home food production of farm families in 1949 was very close to the 1929 level. In the country as a whole in 1949, a slightly smaller proportion of farms had at least one milk cow and a slightly larger proportion had gardens than in 1929. Considering a possible continuation of the downward trend since World War II, it is possible that today home food production on farms is lower than during the late twenties.

These data on the proportion of farms with each of three types of home food production tell only part of the story since they do not show how much garden produce, milk, or meat the farm families produced and used themselves or how much such food contributed to their diets. However, a study of farm diets for one week in the South has shown that those families who did not keep at least one cow consumed very little milk, and had diets low in calcium and riboflavin. Other studies have shown that families with gardens consumed more fruits and vegetables than those without gardens. The reason farm gardens make a great contribution to diets is that fruits and vegetables account for nearly all the ascorbic acid in the diet and a large part of the vitamin A value.

The proportion of farms with each of the three types of home production vary widely among States and regions. Farm gardens continued in 1949 to be more prevalent in the Southeast than in other regions. Ten Southern States had gardens on more than 80 percent of their farms. These estimates cover all tenure groups, including share croppers. In 1929, there were only five Southern States with that high a proportion of farm gardens.

In most regions the proportion of farms with milk cows was about the same or a little less than the proportion having gardens. In the Plains the number with milk cows far exceeded those with gardens; in the Southeast gardens were more frequent. Home production of milk is more prevalent on farms in the Midwest and Plains States than in other areas. In only five States--Iowa, Minnesota, Wisconsin, Nebraska, and Vermont--do at least 80 percent of the farms have one or more milk cows.

Fewer farms produce their own meat than have gardens and milk cows. In no State do as many as 80 percent of the farms slaughter meat animals (chart 16). The States in which a relatively high proportion of farm-operator families--more than 70 percent--slaughter meat animals tend to include those Southern States where gardens are most prevalent and the Midwest and Plains States where milk cows are most prevalent.

Pork is by far the most important home-produced meat except in the West where beef and veal come first. During World War II, when retail meat supplies were rationed, farm family use of home-produced meat increased markedly; following the war it decreased. (See Rural Family Living Charts for 1949 Outlook Conference, pp. 43 and 44.) In 1949, the percent of farms with farm slaughter was lower than in 1939 in each region except the Northeast and the West.

Even in periods of high national income and plentiful food supplies some groups fail to have diets providing recommended amounts of nutrients. Some diets are seriously deficient. Chart 17 shows the percent of farm families in three type-of-farming areas in the South that had diets during the survey week that furnished the recommended amount of five nutrients. (This study was made in late winter and early spring, when home-produced fruit and vegetables might be lowest.)

The nutrients in which most diets were low are those which home-produced foods can help supply: Vitamin A and ascorbic acid from fruits and vegetables, calcium and riboflavin from milk, and protein from milk, eggs, and meat and poultry.

1/ Since Census definition of farm changed markedly from 1944 to 1949 and 1949 data are not available with farms defined as earlier, 1949 data are shown as a range; lower limit of range is Census published data for 1949, and upper limit allows maximum adjustment to earlier definition. The maximum adjustment assumes that the total decline in farms from 1945 to 1950 in a State was due to the change in definition of a farm; this total is added to the Census estimates for 1949 with the further assumption that all such farms had gardens; consequently the resulting percent is an overstatement of the prevalence of gardens. The range of uncertainty as to the proper estimate is most marked in New England States. The midpoint of the range has been used in plotting these data on the accompanying chart.

2/ Includes District of Columbia.

1/ Since Census definition of farm changed markedly from 1939 to 1949 and 1949 data are not available with farms defined as earlier, 1949 data are shown as a range; lower limit of range is 1950 Census published data, and upper limit allows maximum adjustment to earlier definition. The maximum adjustment assumes that the total decline in farms from 1945 to 1950 in a State was due to the change in definition of a farm; this total is added into the Census estimates for 1949 with the further assumption that all such farms had farm slaughter; consequently the resulting percent is an overstatement of the prevalence of farm slaughter. The range of uncertainty as to the proper estimate is most marked in New England States. The midpoint of the range has been used in plotting these data on the accompanying chart.

2/ Includes District of Columbia.

HOUSING

The level of farm housing is improving; rapid strides are being made in electrification of farmhouses, in installation of running water and plumbing, and in the modernization of kitchens. Although fewer than half the dwelling units on farms had running water at the time of the 1950 Census, its installation has been proceeding at a rapid rate (chart 18). Only 18 percent of the farmhouses had running water in 1940; in the next 10 years, an additional 25 percent of the farm units got it. The increase was marked in all regions, but greatest gains were made in the Northeast, which already had the highest proportion of dwellings with running water.

The installation of running water in farmhouses is repeating the history of farm electrification. At the present time, installation of running water is about 5 years behind electrification; the percentage of farmhouses with running water in 1950 was about the same as the percentage of farms with electricity in 1945. (See Rural Family Living Charts for 1951 Outlook Conference, p. 67.) Since electricity is a prerequisite to piped running water on many farms, a lag is to be expected. It is probable that farm installation of running water will continue at a rapid pace.

In each State more than 60 percent of the farms were electrified as of June 30, 1951, and in 20

States 90 percent or more of the farms were electrified (chart 19). For the United States as a whole, the proportion was 84 percent. Areas still having a relatively low proportion of farms with electricity are some parts of the South and some of the Great Plains and Mountain States. The greatest shift since 1945 in the relative rank of regions was made by the East North Central States, which, with the Middle Atlantic States, now has the highest average, 94 percent. No longer do Western farmers rank first in this respect. Half of the farms in the East North Central States have obtained electricity since 1945. The proportion was almost as high in the three Southern Divisions, although the increase did not change their relative rankings.

Electrification of the Nation's farms has continued since 1935 at a remarkably even rate in view of changing supply and other economic conditions. There was some acceleration immediately before World War II and some falling off during the war. Since then, the rate has been somewhat more rapid than in the prewar years.

At the time of the 1950 Census, nearly two-fifths of the farm families had telephones. The Rural Electrification Administration telephone program was just getting underway at the time and the number of telephones had not been appreciably affected by it.

Data on selected housing facilities and household equipment of rural farm families with net income between \$1,000 and \$5,000 in Lee and Jones Counties, Mississippi, in 1945 suggest that housing of families on residential farms may be better than that of the group of families on commercial or part-time farms (chart 20). In this study, residential farms are defined as those with less than \$200 farm sales in the year, and commercial or part-time farms as those units with at least \$200 worth of farm products sold. Average money income was approximately \$2,000 for each of the two farm groups. Most of the families studied were white owners or tenants other than share croppers. These findings also apply when the data are restricted to owners in the two groups.

Nearly half the families on these residential farms had running water in their dwelling and almost as many had a refrigerator. Among commercial or part-time farms nearly a third had running water and the same proportion had a refrigerator. Considerably fewer families in each group had tub or shower, indoor toilets, or power-driven washing machines, but the relationships between the two groups were similar to those found for running water and refrigerators. Differences between the two groups can be explained in part by differences in distance from a population center and differences in the availability of electricity. Undoubtedly differences in consumption standards are involved also.

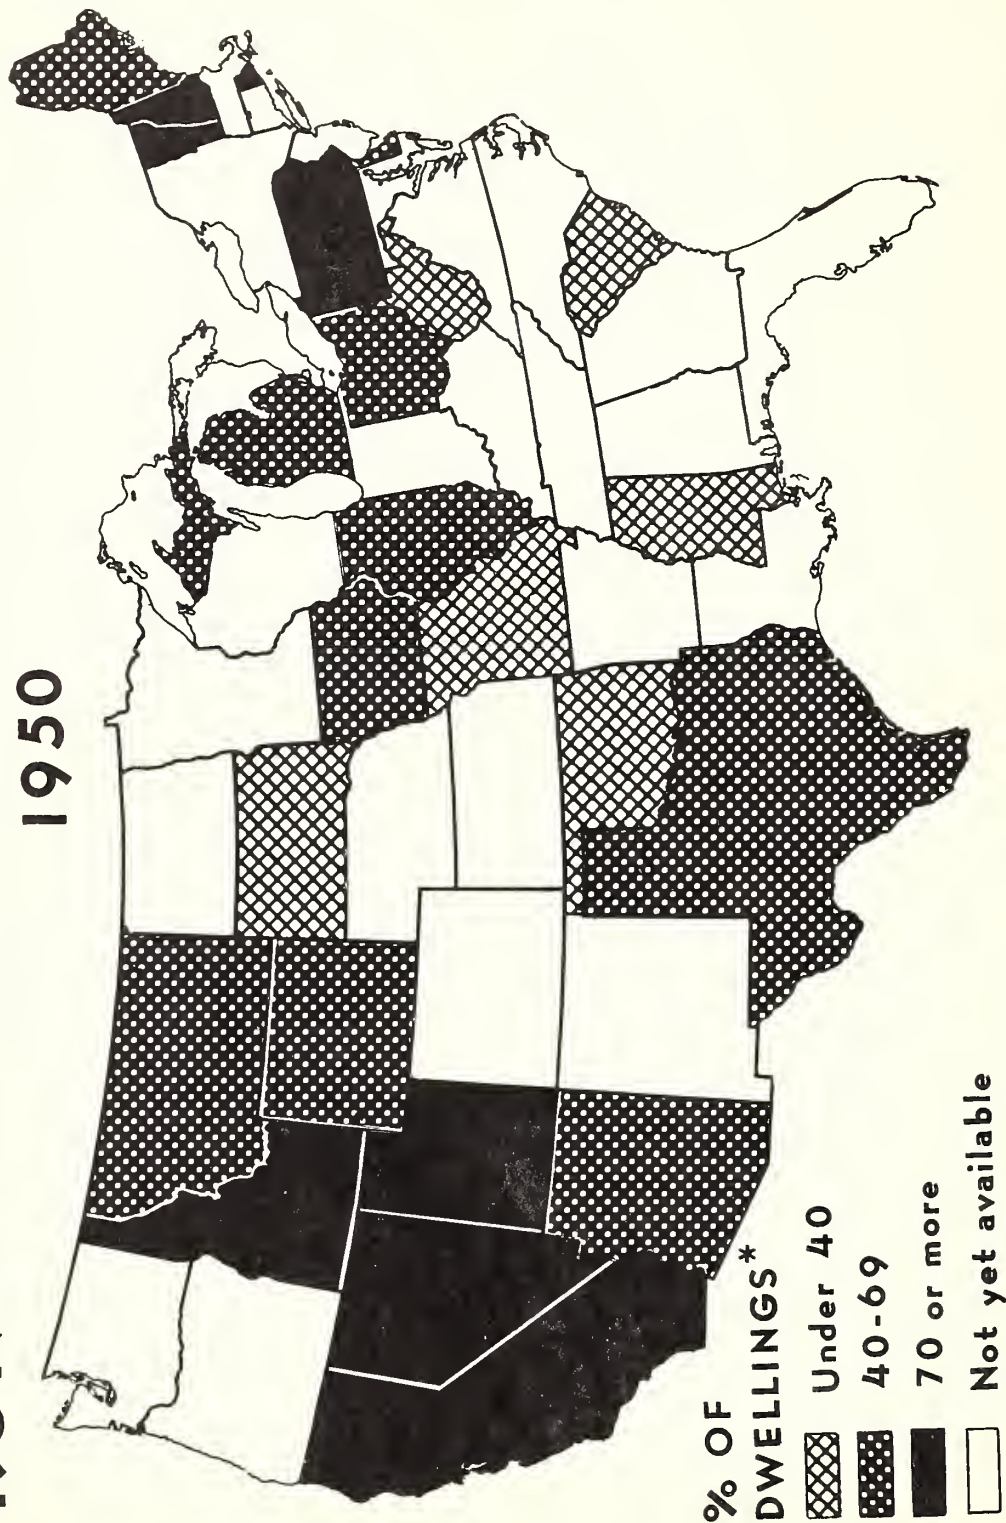

Although the installation of running water and electricity is improving many farmhouses, the older houses may need repair and structural

changes to make them better suited to present day needs. More than half of all houses now standing on rural farms are over 30 years old (chart 21). This is a larger proportion than is found among urban and rural nonfarm dwelling units.

Of the houses standing in 1950, relatively fewer farm than nonfarm dwelling units were built in the 10 preceding years; only 14 percent of the rural farm units were built from 1940 to 1950 compared with 22 percent of the urban and rural nonfarm. The greatest expansion during the decade was in rural nonfarm building and is related to suburban growth. However, urban building, as well as suburban, was at a relatively higher level than rural farm building between 1940 and 1950.

Although the number of dwelling units standing in 1950 is an inexact measure of the building rates in earlier decades, the data suggest that the disparity between relative building of farm and nonfarm units was much sharper in the 1940 decade than in other recent decades. There seems to have been no disparity in the 1930's, and that of the 1920's was considerably less than the 1940's. The proportion of new units built on rural farms has been relatively even in the last three decades, running from 14 to 18 percent of the units now standing. In contrast, the rate of building in urban areas fell sharply in the 1930 decade, and the rural nonfarm building jumped markedly in the 1940 decade with most of the increase occurring after World War II.

1/ Measured on the basis of calendar years from data on year built. Houses built from January to April 1950, when the Census was taken, are thus counted as 0 years old, and the 0-5 interval covers 5-1/4 years, whereas all other intervals are multiples of 5 years.

2/ All dwelling units on farms, not just dwellings of farm operators.

Source: U. S. Bureau of the Census. 1950 Census of Housing, Series HC-5, No. 2

HOUSEHOLD EQUIPMENT

Most families cannot afford to electrify their farm and buy several pieces of major electrical household equipment at the same time. A large proportion, however, buy at least one major item or install a water system in the first or second year; the proportion buying in any one subsequent year is smaller (chart 22).

The timing of farm-family purchases of three types of electrical household equipment and a water system in the years following electrification of the farm is shown by a survey in 1950 of farm operators other than share croppers in the Clay Hills area of Mississippi. All farm operators surveyed had obtained electric power before 1949. Purchases of refrigerators and installation of an electric water system were highest the first year after electrification and fell off thereafter. Purchases of electric washing machines and cook stoves were highest the second year and then fell each subsequent year.

The order in which these items are bought determines whether purchases of a given article are at their peak in the first or second year. In this Mississippi area nearly all refrigerators bought were the first piece of equipment obtained after electrification (table, p. 59). On the other hand, about half the washing machines and one-third the cook stoves were first purchases.

The order of preference undoubtedly results from the interaction of many factors. Climatic conditions and the availability of domestic labor tend to make the refrigerator preferred over the washing machine in the South. What families already own in the way of nonelectric equipment also affects their choice of which items to buy first.

At the time of the survey 88 percent of the families had an electric refrigerator, 51 percent an electric washing machine, 35 percent an electric water system, and 21 percent an electric cook stove. The market for such equipment and facilities is not exhausted for many years after electrification of a rural area.

The generalizations from these special tabulations would probably hold for other areas; however, special characteristics of the area and period covered may have influenced the detailed preferences shown. The Clay Hills area of Mississippi has long been one of small farms, most of which depend largely on cotton for income. Among the farms surveyed, the increase in electrification was particularly sharp in 1948, and only a few of the sample farms had received power as early as 1930. At the time of the survey, income of the families who got electricity early was higher than that of those who had obtained it recently. It is probable that this

difference in income carried back in part to the period of electrification. The findings from the special tabulations of these data are also limited by the fact that preference of families and the types and quantity of electrical household equipment on the market were not the same throughout the period. The major findings for the most part, however, are supported by the purchasing behavior of those families receiving electrical service in any one of the years following World War II.

Ownership of electrical household equipment by farm families shows strong regional differences. The proportion of farm families owning an electric washing machine is highest in the Northeast and Northwest and lowest in the South (chart 23). The pattern of ownership of home freezers is similar although far fewer farm families own freezers. In 1950, nearly 60 percent of all farm families reported owning a washing machine but only 12 percent had freezers.

Comparison of the data on ownership of electric washing machines with the material in the preceding section on electrification of farms indicates that in some States fewer than half the electrified farms have electric washing machines; in other States there are almost as many electric washing machines as electrified farms. The disparity between equipment owned and extent of electrification is usually greatest in the States in which the proportion of electrified farms is low.

From these facts it is evident that factors other than the extent of electrification influ-

ence the ownership of electrical equipment. In general, States with a high level of ownership have had electricity on farms longer, and consequently farm families have had more time to acquire equipment. A high level of income is associated with a high level of equipment ownership as well as with electrification of farms. As noted above, climatic conditions and the availability of household help in some sections affect choices of equipment.

The effect of income on consumption of electricity is shown by a study of Eastern Iowa farm families in 1947 (chart 24). On farms electrified 5 years or more those families in the highest income groups used more than three times as many kilowatt hours of electricity for household operation as those in the lowest income groups. Similar increase with income was also found in Kansas in 1948 and in North Dakota in 1949.

Farm electrification is often discussed primarily in terms of its value in increasing farm income, but its use by the farm family should not be underestimated. In the three areas studied, from 80 to 90 percent of all electricity consumed on the farm was used in the home.

In Iowa where milking machines and lighting in barns and poultry houses increase consumption, the proportion of kilowatt hours used in farming operations was nearly 20 percent, whereas Kansas wheat farmers used only 10 percent for farming operations. In spite of such variations with type of farming, lighting the farm home and operating household equipment consumes much more electricity than farm operations.

1/ Time is measured from calendar year of electrification to calendar year of purchase.

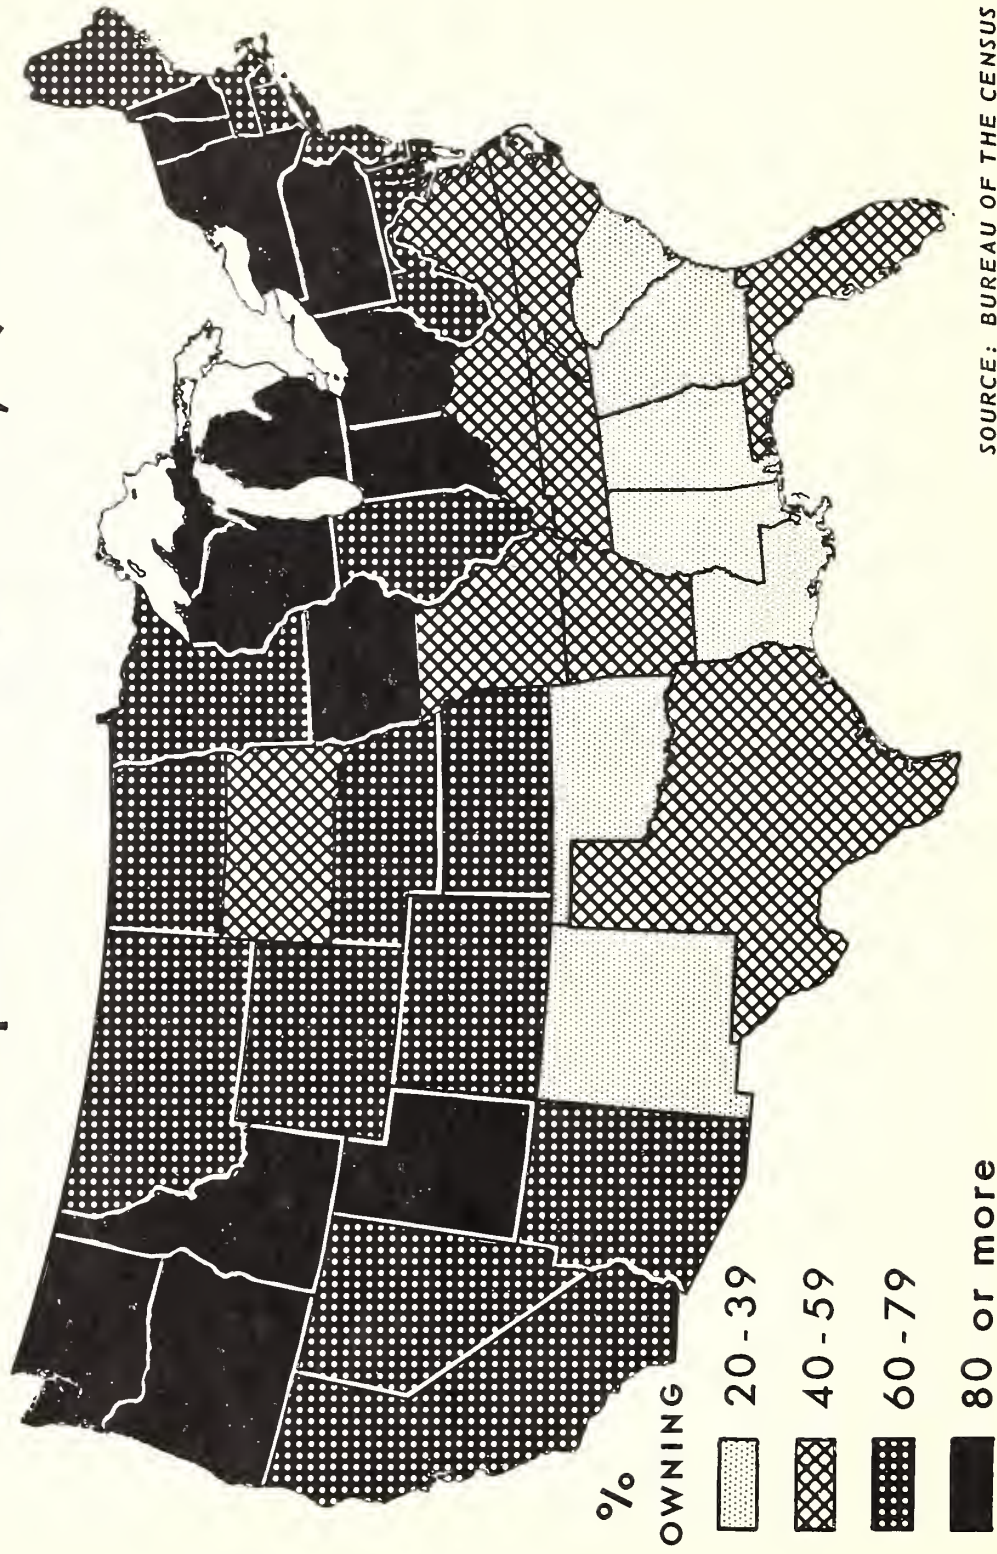

2/ The sum of the ranked purchases of a given item does not always equal the total purchases of the item because for a few cases the order of purchase could not be established. Items bought in the same calendar year are considered to have tied as to ranking and the family is counted as having more than one item of that rank. Consequently conclusions as to the proportion of families having two, three, and four of the specified items cannot be drawn from data for second, third, and fourth purchases.

3/ Gross farm income, including value of home-produced food used, plus cash income from nonfarm sources.

1/ Electrical Merchandising (vol. 83, No. 1, p. 74, January 1951) estimates that there were 1,285,000 gas engine washing machines in use as of January 1, 1951. These can be assumed to be primarily in unelectrified dwellings and dwellings recently electrified, and ownership is concentrated in farm and rural nonfarm households. If 50 to 90 percent of the total number of such machines are in farm households, an additional 12 to 20 percent of farm-operator families would have washing machines.

2/ Includes District of Columbia.

CLOTHING

That farm family consumption habits are becoming more and more similar to those of city families is indicated by a recent study in Minnesota. Clothing practices of farm and city families were found to be not widely different when occupational clothing needs were taken into account. For this analysis, the clothing inventories, quantities purchased in a year, and clothing expenditures of city husbands who wore work clothes at work were compared with the clothing of farm operator husbands. The clothing of city wives who had little or no employment outside the home was compared with the clothing of farm wives.

Taking all types of clothing into consideration--coats, hats, jackets, suits, shoes, gloves, hosiery, and underwear (and weighting each item according to its importance in the wardrobe as indicated by average prices paid)--the farm hus-

bands were found to purchase about 90 percent as many garments as the city men in a single year, and the farm wives about 85 percent as many garments as the city wives (chart 25).

There was considerable variation among the types of garments, however. The farm men purchased more of most types of work clothing than the city husbands, and less of the garments that would be considered dress wear by both of these groups. However, even among the items of dress clothing, the average number of garments purchased by farm husbands was not far below that of the city group. For instance, the farm husbands purchased about 90 percent as many dress gloves and hats as did the city men and about three-quarters to five-sixths as many dress shirts, heavy jackets, and overcoats. The items that the farm men purchased relatively few of were separate trousers, dress shoes, and dress socks.

House dresses, other dresses, and shoes were purchased in about equal amounts by the farm and city wives who had little employment outside the home. The farm wives purchased approximately 80 percent as many hats, light coats, heavy coats, blouses, handbags, and long hosiery as did the city wives. They purchased considerably fewer suits and separate skirts and relatively more overalls, rubbers, and sweaters.

When the average numbers of articles owned are summed and weighted according to their importance in the wardrobe, the clothing inventories of the farm husbands are found to be about 85 percent as large as the inventories of the city men. The farm wives owned about 70 percent as much clothing as the city wives. Thus the discrepancy in the size of the wardrobes of the farm and city husbands and wives is somewhat greater than in the numbers of garments purchased in a year.

Because the farm men and women in the Minnesota study paid less per garment than did the city men and women, the differences between total clothing expenditures of the two groups in a year are greater than differences in quantities purchased. Furthermore, the differences in prices paid were more for the wives than the

husbands; the farm wives paid prices only about two-thirds as great as the city wives. The farm men spent close to \$80 for all clothing in a year (at 1948-49 prices), whereas the city men spent about \$100 (chart 26). The farm wives, on the other hand, spent about \$90 whereas the city wives spent about \$160.

It is likely that the biggest change in the years to come in farm family clothing spending patterns will be in the expenditures of the wives. If the income situation of farm families remains reasonably good or if farm income increases further, the women will probably expand their spending for clothing more than the men.

The importance of holding constant the occupational needs of farm and city groups can be seen by a comparison of the relationships between the farm group and all city husbands and wives in the study rather than confining the comparison to city husbands who wore work clothes at work and city wives who had little or no employment. While the differences between the farm husbands or wives and all city husbands or wives were greater in each instance (table, p.67), the largest differences were found in annual expenditures (table, p. 69).

EDUCATION

Educational attainment of the adult population has shown marked improvement through the years. Evidence of this is the fact that in 1950 the proportion of young adults who had completed elementary school, high school, or college was higher than the proportion of middle-aged or older adults who had reached the same educational levels (chart 27). Comparison of younger and older groups indicates that the greatest improvement has occurred at the high school level. The proportion of adults 25-34 years old who had completed high school in 1950 was nearly three times the proportion of those 65 and over. For elementary school, the proportion was about one and a half times as great for the younger as for the older group. These data do not present an exact measure of progress in education because not all factors have been taken into account.

While the war interrupted the education of many men, over-all gains were made in 1940-50 even by the age group most likely to have been affected--those 25 to 34 years of age (table, p. 73). But the increase would probably not have been so great had not veterans' allowances encouraged school attendance during the years 1946 to 1950.

When adults of a given age group are compared, a lower proportion of those residing on farms than of those residing in urban areas are found to have completed elementary school, high school, or college. (See chart 28 and table, p. 75.) Even among the young adults, three-quarters of

those residing on farms in comparison with almost nine-tenths of those in urban areas had completed elementary school in 1950. Only a third of those on farms had completed high school in contrast with well over half of those in urban areas. Three percent of the young farm adults, 5 percent of the young rural nonfarm adults, and 9 percent of the young urban adults had completed college.

However, these data do not present a clear-cut contrast of the education provided for young people reared in rural and urban areas. Because of migration and differences in mortality rates, somewhat different results would probably be obtained by studying educational attainment of individuals reared in an area rather than by studying, as here, attainment of individuals residing in an area at the time of the Census.

A larger proportion of women than of men at each age level had completed elementary school and high school, but men were ahead in the percentage who had completed college. That this is not simply a postwar phenomenon is indicated by the fact that the same general statement applies to the figures for 1940.

Comparison of men and women of similar age and color or residence reveals that the women were more likely than the men to have completed elementary school and high school in 1950 but, except on farms, less likely than men to have completed college.

Educational attainment of the white adults of a given age group and sex was decidedly higher than that for nonwhite adults of similar age and sex. Eighty-six percent of young white males had completed elementary school in contrast with 55 percent of young nonwhite males. Similar comparisons for the completion of high school were 53 and 20 percent and for the completion of college, 10 and 3 percent.

Since nonwhites made up about the same proportion of the young adult groups in both farm and urban populations, it appears that their low educational attainment was not responsible for the lower attainment of the young farm adults.

Certain changes that have been occurring in the rural schools should help to increase the percentage of farm children who complete elementary school and high school, as well as college. A comparison of data for the school years 1935-36 and 1947-48 shows that during this period the rural schools were approaching the expenditure levels of the urban schools. Although the average salary of the instructional staff in 1935-36 in the rural schools was less than half of that in the urban schools, by 1947-48 it had climbed to two-thirds of that in urban schools (chart 29). This was achieved during a period of rising salaries for all teachers; but the rate of increase in salaries of rural teachers was greater than that of urban teachers. The average salary of rural instructional staff about doubled between the school years 1941-42 and 1947-48 whereas the average urban salary increased by about half.

Total current expenditure (excluding purchase of land, buildings, and equipment) per pupil in the rural schools in 1935-36 was two-thirds of that in the urban schools. By 1947-48 rural per pupil expenditure had climbed to 84 percent of the urban. Expenses for transporting children to and from school tend to be high in some rural school systems, and transportation of children in rural areas has increased due to consolidation of schools.

Part of the relatively greater increase in total current expenditure per pupil in rural than in urban areas may be due to an increase in the average length of the school term. In 1947-48 the rural school term was only 11 days short of the urban term (table, p. 77), but in 1935-36 it was 16 days short.

Capital outlay per pupil actually was higher for rural than for urban schools in the three years studied (table, p. 77). This may be related to the consolidation of the smaller school districts, to new building in suburban developments which are sometimes classified as rural, and to the relatively small enrollment at some rural schools.

Provision for transportation of the pupils seems largely to have overcome previous poor attendance records in rural areas. Both in 1941-42 and in 1947-48 the percentage of pupils enrolled who attended daily was about the same or slightly higher in the rural than in the urban areas.

CENSUS DEFINITIONS

Household and family.--In the 1950 Census the group of persons or the single person occupying a dwelling unit constitutes a household. In addition to the head of the household and his family, the household includes all unrelated persons such as lodgers, guests, and employees living in the dwelling unit. Institutions, hotels, and large rooming houses, which are not dwelling units, are considered to be quasi households and are not included in tabulations of households.

The family is a group of two or more persons related by blood, marriage, or adoption, residing together.

The number of households must coincide with the number of occupied dwelling units, but the number of families may differ. Households composed of a person living alone or of unrelated persons contain no family, but the household may contain more than one family when there is a group of related lodgers, guests, or employees present. On the other hand, a family may comprise persons in a quasi household as well as in a household.

Households in 1950 are comparable with families or private households in the 1940 Census. The definition of family used in 1950 differs from that used prior to 1947 and decreases the count of families. The most important difference is the elimination of persons living alone or with nonrelatives from the count of families.

Urban and rural residence.--In the 1950 Census the urban area is defined to include all places of 2,500 or more population, whether or not they are incorporated, and the densely settled urban fringe around cities of 50,000 or more. All remaining areas are classified as rural. In the 1940 Census incorporated places of 2,500 or more and areas classed as urban under special rules relating to population size and density were classified as urban, and all remaining areas were classed as rural.

Farm and nonfarm residence.--The 1950 Censuses of Population and Housing include in the farm population all persons living on farms except those paying cash rent for their house and yard only, and person in institutions, camps, hotels, and motels located on farms. Both groups were included in the farm population in previous Censuses. In both Censuses the respondent indicated whether the place was on a farm.

Farms.--The 1950 Census of Agriculture defines a farm as a place of 3 acres or more that produced \$150 in agricultural products exclusive of home gardens, or a place of less than 3 acres if \$150 was received from the sale of agricultural products. In the 1940 and 1945 Censuses, all units of 3 acres or more were included plus all units of less than 3 acres that had \$250 worth of production, including production for home use.
